/**
 * Driver class for j-- compiler using JavaCC front-end. This is the main entry
 * point for the compiler. The compiler proceeds as follows:
 *
 * (1) It reads arguments that affects its behavior.
 *
 * (2) It builds a scanner.
 *
 * (3) It builds a parser (using the scanner) and parses the input for producing
 * an abstact syntax tree (AST).
 *
 * (4) It sends the preAnalyze() message to that AST, which recursively descends
 * the tree so far as the memeber headers for declaring types and members in the
 * symbol table (represented as a string of contexts).
 *
 * (5) It sends the analyze() message to that AST for declaring local variables,
 * and cheking and assigning types to expressions. Analysis also sometimes
 * rewrites some of the abstract syntax trees for clarifying the semantics.
 * Analysis does all of this by recursively descending the AST down to its
 * leaves.
 *
 * (6) Finally, it sends a codegen() message to the AST for generating code.
 * Again, codegen() recursively descends the tree, down to its leaves,
 * generating JVM code for producing a .class or .s (SPIM) file for each defined
 * type (class).
 */
